

Q3 Disclosure score, company size and climate exposure (n = 50)

Baseline group (n = 16): companies whose principal business creates no concentrated climate exposure, comprising software, biotechnology, medical devices, gaming, professional services, telecommunications and retail. It is a residual category, not a benchmark, and is internally heterogeneous. In dummy coding one group must be omitted, and every coefficient in panel (b) is read against it: positive means higher than the baseline at the same company size. The choice of baseline is arbitrary and does not change model fit or predicted scores. Black markers hold size constant as log10 index weight; grey markers repeat the model with size as tertiles (small, mid, large), a robustness check on how size is measured. In the lower three rows black and grey estimate the same quantity. In the top row they do not: black is the change per tenfold increase in weight, grey is the largest tertile against the smallest.
